# Introduction to Computer Security

Discussion 2

## Question 1 Software Vulnerabilities

For the following code, assume an attacker can control the value of basket, n, and owner\_name passed into search\_basket.

This code contains several security vulnerabilities. **Circle** *three* **such vulnerabilities** in the code and briefly explain each of the three on the next page.

```
struct cat {
2
      char name [64];
3
      char owner [64];
4
      int age;
5
  };
  /* Searches through a BASKET of cats of length N (N should be less
     than 32). Adopts all cats with age less than 12 (kittens).
     Adopted kittens have their owner name overwritten with OWNER_NAME
      . Returns the number of kittens adopted. */
  size_t search_basket(struct cat *basket, int n, char *owner_name) {
      struct cat kittens [32];
9
       size_t num_kittens = 0;
10
       if (n > 32) return -1;
11
12
      for (size_t i = 0; i \le n; i++) {
           if (basket[i].age < 12) {</pre>
13
14
               /* Reassign the owner name. */
15
               strcpy(basket[i].owner, owner_name);
               /* Copy the kitten from the basket. */
16
               kittens[num_kittens] = basket[i];
17
               num kittens++;
18
               /* Print helpful message. */
19
20
               printf("Adopting kitten: ");
               printf(basket[i].name);
21
               printf("\n");
22
23
           }
24
       /* Adopt kittens. */
25
       adopt_kittens(kittens, num_kittens); // Implementation not shown
26
27
      return num kittens;
28 }
```

#### 1. Explanation:

**Solution:** Line **12** has a fencepost error: the conditional test should be i < n rather than i <= n. The test at line **11** assures that **n** doesn't exceed 32, but if it's equal to 32, and if all of the cats in **basket** are kittens, then the assignment at line **17** will write past the end of **kittens**, representing a buffer overflow vulnerability.

### 2. Explanation:

**Solution:** At line 12, we are checking if  $i \le n$ . i is an unsigned int and n is a signed int, so during the comparison n is cast to an unsigned int. We can pass in a value such as n = -1 and this would be cast to 0xffffffff which allows the for loop to keep going and write past the buffer.

### 3. Explanation:

**Solution:** On line **15** there is a call to strcpy which writes the contents of owner\_name, which is controlled by the attacker, into the owner instance variable of the cat struct. There are no checks that the length of the destination buffer is greater than or equal to the source buffer owner\_name and therefore the buffer can be overflown.

**Solution:** Another possible solution is that on line **21** there is a printf call which prints the value stored in the name instance variable of the cat struct. This input is controlled by the attacker and is therefore subject to format string vulnerabilities since the attacker could assign the cats names with string formats in them.

Some more minor issues concern the **name** strings in **basket** possibly not being correctly terminated with '\0' characters, which could lead to reading of memory outside of **basket** at line **21**.

Describe how an attacker could exploit these vulnerabilities to obtain a shell:

**Solution:** Each vulnerability could lead to code execution. An attacker could also use the fencepost or the bound-checking error to overwrite the RIP and execute arbitrary code.

#### Question 2 Hacked EvanBot

Hacked EvanBot is running code to violate students' privacy, and it's up to you to disable it before it's too late!

```
#include <stdio.h>

void spy_on_students(void) {
    char buffer [16];
    fread(buffer, 1, 24, stdin);

int main() {
    spy_on_students();
    return 0;
}
```

The shutdown code for Hacked EvanBot is located at address <code>Oxdeadbeef</code>, but there's just one problem—Bot has learned a new memory safety defense. Before returning from a function, it will check that its saved return address (rip) is not <code>Oxdeadbeef</code>, and throw an error if the rip is <code>Oxdeadbeef</code>.

Clarification during exam: Assume little-endian x86 for all questions.

Assume all x86 instructions are 8 bytes long. <sup>1</sup>Assume all compiler optimizations and buffer overflow defenses are disabled.

The address of buffer is 0xbffff110.

Q2.1 (3 points) In the next 3 subparts, you'll supply a malicious input to the fread call at line 5 that causes the program to execute instructions at 0xdeadbeef, without overwriting the rip with the value 0xdeadbeef.

The first part of your input should be a single assembly instruction. What is the instruction? x86 pseudocode or a brief description of what the instruction should do (5 words max) is fine.

#### **Solution:** jmp \*0xdeadbeef

You can't overwrite the rip with <code>Oxdeadbeef</code>, but you can still overwrite the rip to point at arbitrary instructions located somewhere else. The idea here is to overwrite the rip to execute instructions in the buffer, and write a single jump instruction that starts executing code at <code>Oxdeadbeef</code>.

Grading: most likely all or nothing, with some leniency as long as you mention something about jumping to address <code>Oxdeadbeef</code>. We will consider alternate solutions, though.

<sup>&</sup>lt;sup>1</sup>In practice, x86 instructions are variable-length.

Q2.2	(3 points) The second part of your input should be some garbage bytes. How many garbage byte do you need to write?						
	(G) 0	(H) 4	(I) 8	<b>●</b> (J) 12	(K) 16	(L) —	
		•		n the previous partie the sfp, for a to		•	
Q2.3	(3 points) What are the last 4 bytes of your input? Write your answer in Project 1 Python syntax e.g. \x12\x34\x56\x78.						
	This is the slightly dif	\x10\xf1\xff address of the ju fferent on random dit for writing the	ump instruction mized versions o		of <b>buffer</b> .(The	address may be	
Q2.4	(3 points) When does your exploit start executing instructions at 0xdeadbeef?  (G) Immediately when the program starts  (H) When the main function returns  (I) When the spy_on_students function returns  (J) When the fread function returns  (K) —  (L) —						
	spy_on_s	-	on returns, the	e rip of spy_ e program will			

# Question 3 I Understood that Reference!

Consider the following vulnerable C code:

```
void vulnerable(int start, char *ptr) {
       ptr[start] = ptr[3];
 3
       ptr[start + 1] = ptr[2];
 4
       ptr[start + 2] = ptr[1];
5
       ptr[start + 3] = ptr[0];
6
7
  void helper(int8_t num) {
9
       if (num > 124) {
10
           return;
11
12
       char arr[128];
       fgets (arr, 128, stdin);
13
14
       vulnerable(num, arr);
15 }
16
17 int main(void) {
18
       int y;
19
       fread(&y, sizeof(int), 1, stdin);
       helper(y);
20
21
       return 0;
22 }
```

#### Assume that:

- You are on a little-endian 32-bit x86 system.
- There is no other compiler padding or saved additional registers.

Write your answer in Python 2 syntax (just like in Project 1).

Q3.1 (3 min) Fill in the stack diagram below, assuming that execution has entered the call to vulnerable:

RIP of main					
SFP of main					
RIP of vulnerable					
SFP of vulnerable					

**Solution:** Nothing too complicated about this stack diagram. Notice that when integer arguments are passed to functions, their values are directly placed on the stack (not pointers, like strings).

# Stack

RIP of main
SFP of main
у
num
RIP of helper
SFP of helper
arr
ptr
start
RIP of vulnerable
SFP of vulnerable

For the rest of this question, assume that the RIP of main is located at 0xbfffdc0c and that your malicious shellcode is located at 0xef302010.

In the next two subparts, construct an exploit that executes your malicious shellcode.

Q3.2 (5 min) Provide an input to the variable y in the fread in main.

For this subpart only, you may write a decimal number instead of its byte representation.

**Solution:** This attack involves noticing that we're indexing into the ptr array using a value that we control (we choose the value of start through the fread call in main). With this, we can think about how to overwrite one of the RIP's present on our stack. There's a catch, though - since start is restricted to values less than 127, and arr is 128 bytes long, we can't write over the RIP of helper; however, we can set start to a negative number to index downwards and overwrite the RIP of vulnerable. That RIP lives three words below the start of the array, so we start at array index -12.

Any number with the final byte set to 'xf4' will work. We want to choose some y such that, when cast to the int8\_t, it becomes -12.

Q3.3 (5 min) Provide an input to the variable arr in the fgets in helper.

**Solution:** We need to reverse the order of the bytes in our new RIP address, since they're read in reverse of our normal direction (starting at ptr[3] and going to ptr[0]). Once this address is placed into the array, it'll be in little-endian format.

 $\xef\x30\x20\x10$ '
